Important Note

Displaying Hidden Details in this Guide

This style guide contains many details that are initially hidden from view. They are marked by the triangle icon, which you see here on your left. Click it now. You should see "Hooray" appear below.

Background

C++ is the main development language used by many of Google's open-source projects. As every C++ programmer knows, the language has many powerful features, but this power brings with it complexity, which in turn can make code more bug-prone and harder to read and maintain.

The goal of this guide is to manage this complexity by describing in detail the dos and don'ts of writing C++ code. These rules exist to keep the code base manageable while still allowing coders to use C++ language features productively.

Style, also known as readability, is what we call the conventions that govern our C++ code. The term Style is a bit of a misnomer, since these conventions cover far more than just source file formatting.

One way in which we keep the code base manageable is by enforcing *consistency*. It is very important that any programmer be able to look at another's code and quickly understand it. Maintaining a uniform style and following conventions means that we can more easily use "pattern-matching" to infer what various symbols are and what invariants are true about them. Creating common, required idioms and patterns makes code much easier to understand. In some cases there might be good arguments for changing certain style rules, but we nonetheless keep things as they are in order to preserve consistency.

Another issue this guide addresses is that of C++ feature bloat. C++ is a huge language with many advanced features. In some cases we constrain, or even ban, use of certain features. We do this to keep code simple and to avoid the various common errors and problems that these features can cause. This guide lists these features and explains why their use is restricted.

Open-source projects developed by Google conform to the requirements in this guide.

Note that this guide is not a C++ tutorial: we assume that the reader is familiar with the language.

Header Files

In general, every .cc file should have an associated .h file. There are some common exceptions, such as unittests and small .cc files containing just a main() function.

Correct use of header files can make a huge difference to the readability, size and performance of your code.

The following rules will guide you through the various pitfalls of using header files.

The #define Guard

All header files should have #define guards to prevent multiple inclusion. The format of the symbol name should be <PROJECT>_<PATH>_<FILE>_H_.

Header File Dependencies

Don't use an #include when a forward declaration would suffice.

Inline Functions

Define functions inline only when they are small, say, 10 lines or less.

The -inl.h Files

You may use file names with a -inl.h suffix to define complex inline functions when needed.

Function Parameter Ordering

When defining a function, parameter order is: inputs, then outputs.

Names and Order of Includes

Use standard order for readability and to avoid hidden dependencies: C library, C++ library, other libraries' .h, your project's .h.

Scoping

Namespaces

Unnamed namespaces in .cc files are encouraged. With named namespaces, choose the name based on the project, and possibly its path. Do not use a *using-directive*.

Nested Classes

Although you may use public nested classes when they are part of an interface, consider a <u>namespace</u> to keep declarations out of the global scope.

Nonmember, Static Member, and Global Functions

Prefer nonmember functions within a namespace or static member functions to global functions; use completely global functions rarely.

Local Variables

Place a function's variables in the narrowest scope possible, and initialize variables in the declaration.

Static and Global Variables

Static or global variables of class type are forbidden: they cause hard-to-find bugs due to indeterminate order of construction and destruction.

Classes

Classes are the fundamental unit of code in C++. Naturally, we use them extensively. This section lists the main dos and don'ts you should follow when writing a class.

Doing Work in Constructors

In general, constructors should merely set member variables to their initial values. Any complex initialization should go in an explicit Init() method.

Default Constructors

You must define a default constructor if your class defines member variables and has no other constructors. Otherwise the compiler will do it for you, badly.

Explicit Constructors

▶ Use the C++ keyword explicit for constructors with one argument.

Copy Constructors

Provide a copy constructor and assignment operator only when necessary. Otherwise, disable them with DISALLOW COPY AND ASSIGN.

Structs vs. Classes

▶ Use a struct only for passive objects that carry data; everything else is a class.

Inheritance

Composition is often more appropriate than inheritance. When using inheritance, make it public.

Multiple Inheritance

Only very rarely is multiple implementation inheritance actually useful. We allow multiple inheritance only when at most one of the base classes has an implementation; all other base classes must be <u>pure interface</u> classes tagged with the Interface suffix.

Interfaces

Classes that satisfy certain conditions are allowed, but not required, to end with an Interface suffix.

Operator Overloading

Do not overload operators except in rare, special circumstances.

Access Control

Make data members private, and provide access to them through accessor functions as needed (for technical reasons, we allow data members of a test fixture class to be protected when using Google Test). Typically a variable would be called foo_ and the accessor function foo(). You may also want a mutator function set_foo(). Exception: static const data members (typically called kFoo) need not be private.

Declaration Order

Use the specified order of declarations within a class: public: before private:, methods before data members (variables), etc.

Write Short Functions

Prefer small and focused functions.

Google-Specific Magic

There are various tricks and utilities that we use to make C++ code more robust, and various ways we use C++ that may differ from what you see elsewhere.

Smart Pointers

If you actually need pointer semantics, scoped_ptr is great. You should only use std::tr1::shared_ptr under very specific conditions, such as when objects need to be held by STL containers. You should never use auto_ptr.

cpplint

Use cpplint.py to detect style errors.

Other C++ Features

Reference Arguments

All parameters passed by reference must be labeled const.

Function Overloading

Use overloaded functions (including constructors) only if a reader looking at a call site can get a good idea of what is happening without having to first figure out exactly which overload is being called.

Default Arguments

We do not allow default function parameters, except in a few uncommon situations explained below.

Variable-Length Arrays and alloca()

▶ We do not allow variable-length arrays or alloca().

Friends

We allow use of friend classes and functions, within reason.

Exceptions

▶ We do not use C++ exceptions.

Run-Time Type Information (RTTI)

We do not use Run Time Type Information (RTTI).

Casting

Use C++ casts like static_cast<>(). Do not use other cast formats like int y = (int)x; or int y = int(x);.

Streams

Use streams only for logging.

Preincrement and Predecrement

Use prefix form (++i) of the increment and decrement operators with iterators and other template objects.

Use of const

▶ We strongly recommend that you use const whenever it makes sense to do so.

Integer Types

Of the built-in C++ integer types, the only one used is int. If a program needs a variable of a different size, use a precise-width integer type from <stdint.h>, such as int16 t.

64-bit Portability

Code should be 64-bit and 32-bit friendly. Bear in mind problems of printing, comparisons, and structure alignment.

Preprocessor Macros

Be very cautious with macros. Prefer inline functions, enums, and const variables to macros.

0 and NULL

▶ Use 0 for integers, 0.0 for reals, NULL for pointers, and '\0' for chars.

sizeof

Use sizeof(varname) instead of sizeof(type) whenever possible.

Boost

▶ Use only approved libraries from the Boost library collection.

C++0x

Use only approved libraries and language extensions from C++0x. Currently, none are approved.

Naming

The most important consistency rules are those that govern naming. The style of a name immediately informs us what sort of thing the named entity is: a type, a variable, a function, a constant, a macro, etc., without requiring us to search for the declaration of that entity. The pattern-matching engine in our brains relies a great deal on these naming rules.

Naming rules are pretty arbitrary, but we feel that consistency is more important than individual preferences in this area, so regardless of whether you find them sensible or not, the rules are the rules.

General Naming Rules

Function names, variable names, and filenames should be descriptive; eschew abbreviation. Types and variables should be nouns, while functions should be "command" verbs.

File Names

Filenames should be all lowercase and can include underscores (_) or dashes (-). Follow the convention that your project uses. If there is no consistent local pattern to follow, prefer "_".

Type Names

Type names start with a capital letter and have a capital letter for each new word, with no underscores: MyExcitingClass, MyExcitingEnum.

Variable Names

Variable names are all lowercase, with underscores between words. Class member variables have trailing underscores. For instance:

my exciting local variable, my exciting member variable .

Constant Names

▶ Use a k followed by mixed case: kDaysInAWeek.

Function Names

Regular functions have mixed case; accessors and mutators match the name of the variable: MyExcitingFunction(), MyExcitingMethod(), my exciting member variable(), set my exciting member variable().

Namespace Names

Namespace names are all lower-case, and based on project names and possibly their directory structure: google awesome project.

Enumerator Names

Enumerators should be named *either* like <u>constants</u> or like <u>macros</u>: either kEnumName or ENUM NAME.

Macro Names

You're not really going to <u>define a macro</u>, are you? If you do, they're like this: MY_MACRO_THAT_SCARES_SMALL_CHILDREN.

Exceptions to Naming Rules

If you are naming something that is analogous to an existing C or C++ entity then you can follow the existing naming convention scheme.

Comments

Though a pain to write, comments are absolutely vital to keeping our code readable. The following rules describe what you should comment and where. But remember: while comments are very important, the best code is self-documenting. Giving sensible names to types and variables is much better than using obscure names that you must then explain through comments.

When writing your comments, write for your audience: the next contributor who will need to understand your code. Be generous — the next one may be you!

Comment Style

File Comments

Start each file with a copyright notice, followed by a description of the contents of the file.

Class Comments

Every class definition should have an accompanying comment that describes what it is for and how it should be used.

Function Comments

Declaration comments describe use of the function; comments at the definition of a function describe operation.

Variable Comments

In general the actual name of the variable should be descriptive enough to give a good idea of what the variable is used for. In certain cases, more comments are required.

Implementation Comments

In your implementation you should have comments in tricky, non-obvious, interesting, or important parts of your code.

Punctuation, Spelling and Grammar

Pay attention to punctuation, spelling, and grammar; it is easier to read well-written comments than badly written ones.

TODO Comments

Use TODO comments for code that is temporary, a short-term solution, or good-enough but not perfect.

Deprecation Comments

▶ Mark deprecated interface points with DEPRECATED comments.

Formatting

Coding style and formatting are pretty arbitrary, but a project is much easier to follow if everyone uses the same style. Individuals may not agree with every aspect of the formatting rules, and some of the rules may take some getting used to, but it is important that all project contributors follow the style rules so that they can all read and understand everyone's code easily.

To help you format code correctly, we've created a settings file for emacs.

Line Length

Each line of text in your code should be at most 80 characters long.

Non-ASCII Characters

Non-ASCII characters should be rare, and must use UTF-8 formatting.

Spaces vs. Tabs

▶ Use only spaces, and indent 2 spaces at a time.

Function Declarations and Definitions

Return type on the same line as function name, parameters on the same line if they fit.

Function Calls

On one line if it fits; otherwise, wrap arguments at the parenthesis.

Conditionals

Prefer no spaces inside parentheses. The else keyword belongs on a new line.

Loops and Switch Statements

Switch statements may use braces for blocks. Empty loop bodies should use {} or continue.

Pointer and Reference Expressions

No spaces around period or arrow. Pointer operators do not have trailing spaces.

Boolean Expressions

When you have a boolean expression that is longer than the <u>standard line length</u>, be consistent in how you break up the lines.

Return Values

▶ Do not needlessly surround the return expression with parentheses.

Variable and Array Initialization

Your choice of = or ().

Preprocessor Directives

Preprocessor directives should not be indented but should instead start at the beginning of the line.

Class Format

Sections in public, protected and private order, each indented one space.

Constructor Initializer Lists

Constructor initializer lists can be all on one line or with subsequent lines indented four spaces.

Namespace Formatting

The contents of namespaces are not indented.

Horizontal Whitespace

Use of horizontal whitespace depends on location. Never put trailing whitespace at the end of a line.

Vertical Whitespace

Minimize use of vertical whitespace.

Exceptions to the Rules

The coding conventions described above are mandatory. However, like all good rules, these sometimes have exceptions, which we discuss here.

Existing Non-conformant Code

You may diverge from the rules when dealing with code that does not conform to this style guide.

Windows Code

Windows programmers have developed their own set of coding conventions, mainly derived from the conventions in Windows headers and other Microsoft code. We want to make it easy for anyone to understand your code, so we have a single set of quidelines for everyone writing C++ on any platform.

Parting Words

Use common sense and BE CONSISTENT.

If you are editing code, take a few minutes to look at the code around you and determine its style. If they use spaces around their if clauses, you should, too. If their comments have little boxes of stars around them, make your comments have little boxes of stars around them too.

The point of having style guidelines is to have a common vocabulary of coding so people can concentrate on what you are saying, rather than on how you are saying it. We present global style rules here so people know the vocabulary. But local style is also important. If code you add to a file looks drastically different from the existing code around it, the discontinuity throws readers out of their rhythm when they go to read it. Try to avoid this.

OK, enough writing about writing code; the code itself is much more interesting. Have fun!
